### Exercise 1: Shell

Shell does not do input processing. The shell just runs programs that exist using the `exec` command. An application layer would need to be placed over top of our shell to implement non system program commands as well as to do things such as making `exit` call `shell.close`. We also no longer use the ruby `shell` class as

### Exercise 2: Timed Printout

Renamed the module to `DelayedAction` from `TimedPrintout` because the module can now handle a delayed block rather than just a delayed print.

Current flaw is that it creates a new process for each delayed action. Tried to change this to using threads but ruby threads don't understand that the C `nanosleep` we are calling is in fact a sleep routine.

### Exercise 3: File Tracker

Changed from planning to use the `inotify` library to a loop that checks for file changes every so often. This was done for simplicity as there was no simple way to call the `inotify` library from ruby.
